1 Same arithmetic, different lines

The cost of a miss against a false alarm sets the line: about 5% for support tickets, 0.3% for clinical intake.

2 Volume decides who decides

Millions of cheap decisions a day: the model decides and people audit. A few costly ones: people decide.

3 Every choice needs a way out

Other, none, not enough information: each domain needs the option that catches what fits nowhere.

4 Measure before you trust

On synthetic support tickets the mock routed 74% correctly and barely ranked urgency. Without labels, you'd never have known.

5 Route only when sure

Routing only confident tickets: 55% of them, 85% right. The rest go to a person.

6 High stakes: order, don't decide

Where a person must make the call, the model's job is the queue: who is seen first, and what to look at.
