

What “learning” means

1 Rules vs learning

A rule is you telling the computer exactly what to do. Rules break when the world has too many exceptions.

2 A model is a learned function

Trained once on examples with answers, then used on new cases where the answer is unknown.

3 Learning = fewer mistakes

Try settings, count mistakes, keep the setting that makes the fewest. That is learning, in miniature.

4 But “fewest” can be useless

With few attacks, the best-scoring rule flags almost nothing: 1,487 mistakes, against 1,515 for flagging nothing at all. We asked the wrong question.

5 Answers should be chances

The same score can be an attack or not. A good model says how likely.

6 Generate or decide

LLMs write answers word by word. System One models like Jev return typed answers with probabilities, in one pass.

The map: a story, not a list

Rules weren't enough, so machines learned from data. Harder problems needed bigger models. Now we build systems that act.
